### Abstract

Takeoff speeds are a crucial piece of information which are required before commencing any flight. A technique to calculate V-Speeds for aircraft using appropriate interpolation in RTOW charts is proposed in this paper. The RTOW (Regulated Takeoff Weight) charts provide a valuable source of data for evaluating takeoff speeds for different weather conditions for a particular runway at a particular airport. This paper applies interpolation techniques to accurately interpret the data from the RTOW chart and hence precisely calculate the V-Speeds for different temperature and wind speed values.

**Keywords:** Aviation Industry, Takeoff Speeds, Air Travel, RTOW Chart

### 1. Introduction

Recent papers have provided with application of interpolation in aviation such as wind analysis, and the time interpolation method on the altitude optimization algorithm for FMS CMA-9000. [1],[2],[3].

This paper identifies techniques to use interpolation in RTOW charts to calculate the optimum takeoff speed for an aircraft for suitable weather conditions. V<sub>1</sub>, V<sub>R</sub> and V<sub>2</sub> speeds have their own functions, as explained in the paper's later sections. This paper talks about new developments related to the application of interpolation in calculating the appropriate takeoff speeds based on changing meteorological conditions.

Being an important stage of a flight, it is a must to guarantee a safe takeoff. To do the same, calculating V-speeds must be done accurately while keeping in mind all the meteorological data, the aircraft payload, and fuel weight. This speed depends on aircraft type, weight, and meteorological conditions. For example, an A320-216S with CFM 56-5B6 engines, a takeoff weight of 78.2 tons departing from Hyderabad runway 27R Dry runway, with flaps 1+F, TOGA, without anti-ice and air-conditioning at an outside air temperature of 29 degrees Celsius, and calm winds will have its V<sub>1</sub>, V<sub>R</sub> and V<sub>2</sub> speeds as 152, 160 and 161, respectively. The interpolation techniques used in this paper include Newton Forward Interpolation, Newton Backward Interpolation, Newton Divided Difference Interpolation, Gauss Interpolation and Bessel Interpolation. Python formulas are used to carry out the necessary calculations. [4]

This paper is organized as follows, explanation of different V-Speeds during takeoff, theoretical explanation of various mentioned interpolation methods, RTOW Chart for Hyderabad and python formulas for different interpolation techniques. It is followed by the result of the Numerical Analysis and the conclusion which contains the interpretation of those results. It is proceeded by the list of references which ends the paper.

### 2. Takeoff Speeds

For a safe takeoff execution, 3 takeoff speeds are calculated. These V-speeds depend on several factors including aircraft type, weight, available runway length for departure, degree of flap extension, engine thrust and defilements on the surface of the runway. V-speeds are defined as follows:

### 2.1. $V_1$ Speed

$V_1$ : Also known as the takeoff decision speed, is described as the speed after which takeoff should not be aborted in any case. The takeoff will continue even if the aircraft has reached its  $V_1$  speed even if there is an engine failure or tyre burst, etc. Aborting the takeoff after  $V_1$  will, by definition, result in the aircraft being unable to stop before the runway end and suffering a runway overrun.

### 2.2. $V_R$ Speed

$V_R$ : It is the speed when rotation is commenced to carry out a safe takeoff. It is the speed when the pilot pulls back the control column to pitch the nose up. Or it is the speed when the nose wheel (frontmost wheel) of the airplane is lifted from the ground.

### 2.3. $V_2$ Speed

$V_2$ : Also called “take-off safety speed”, it refers to the speed of safe climb at 200 feet per minute that can be carried out with 1 engine inoperative [5]

Fig. 1: Takeoff Speeds

## 3. Analysis of RTOW Chart

For the calculation of takeoff speeds, data used in this paper is provided by an RTOW (Regulated takeoff weight) chart. Let us assume that an Airbus A320-216S with CFM56-5B6 Engines, is departing Hyderabad runway 27R with flaps 1+F, and TOGA thrust. The QNH (Air Pressure) is 1013.25 HPA, and the runway is dry. Then, according to the RTOW chart, the  $V_1$  speed,  $V_R$  speeds and  $V_2$  speeds of that aircraft with varying temperatures would be gives as

4. Applying Interpolation in RTOW Chart

#### 4.1. Calculating v-speeds by interpolating for varying temperature

To calculate 3 v-speeds at 15 degrees Celsius at a tailwind of 10 knots, Newton Forward Interpolation is used as the value at which interpolation is carried out, is near the beginning of the table. The python code for Newton Forward Interpolation [6] used to calculate the  $V_1$ ,  $V_R$  and  $V_2$  speeds is given below which gives the V-speeds to be 146.040817, 158.726703 and 153.283333 knots at 15 degrees centigrade with 10 knots of tailwind.

```
def calculate(u,n):
    tmp=u
    for i in range(1,n):
        tmp=tmp*(u-i)
    return tmp
def factorial(n):
    fact=1
    for i in range(2,n+1):
        fact=fact*i
    return fact
def newton_forward():
    global n,x,y,v
    for i in range(1,n):
        for j in range(0,n-1):
            y[j][i]=y[j+1][i-1]-y[j][i-1]
        for i in range(0,n):
            print(round(x[i],6),end="\t")
        for j in range(0,n-1):
            print(round(y[i][j],6),end="\t")
        print()
        s=y[0][0]
        u=(v-x[0])/(x[i]-x[0])
        for i in range(1,n):
            s=s+(calculate(u,i)*y[0][i])/factorial(i)
        print("value at ",v," is ",s)
    n=int(input("Enter the number of elements: "))
    x=[]
    y=[[0 for i in range(n)]
        for j in range(n)]
    print("Enter the values of x: ")
    for i in range(0,n):
        x.append(float(input()))
    print("Enter the values of y: ")
    for i in range(0,n):
        y[i][0]=float(input())
    v=float(input("Enter the value of interpolation: "))
    newton_forward()

#### 4.2. Calculating v-speeds by interpolating for varying wind speeds

To calculate 3 v-speeds at 17 degrees Celsius, but at a headwind of 2 knots, Bessel Interpolation is used since the value at which interpolation needs to be carried out, is near the centre of the table.

The python code for Bessel Interpolation [6] is :

```

def ucal(u, n):
    if (n == 0):
        return 1
    temp = u
    for i in range(1, int(n / 2 + 1)):
        temp = temp * (u - i)
    for i in range(1, int(n / 2)):
        temp = temp * (u + i)
    return temp
    
```

```

def fact(n):
    f = 1
    for i in range(2, n + 1):
        f *= i
    return f
n = 6
x = [25, 26, 27, 28, 29, 30]
y = [[0 for i in range(n)]
      for j in range(n)]
y[0][0] = 154
y[1][0] = 159
y[2][0] = 163
y[3][0] = 165
y[4][0] = 167
for i in range(1, n):
    for j in range(n - i):
        y[j][i] = y[j + 1][i - 1] - y[j][i - 1]
for i in range(n):
    for j in range(n - i):
        print(y[i][j], "\t", end = " ")
    print("")
    value = 2
    sum = (y[2][0] + y[3][0]) / 2
    k = 0
    if ((n % 2) > 0):
        k = int(n / 2)
    else:
        k = int(n / 2 - 1); # origin for even
    u = (value - x[k]) / (x[1] - x[0])
    for i in range(1, n):
        if (i % 2):
            sum = sum + ((u - 0.5) *
                ucal(u, i - 1) *
                y[k][i]) / fact(i)
        else:
            sum = sum + (ucal(u, i) * (y[k][i] +
                y[k - 1][i]) / (fact(i) * 2))
            k -= 1
    print("Value at", value, "is", round(sum, 5));

```

According to this code, the value of  $V_1$ ,  $V_R$ ,  $V_2$  are 156.1456, 163.0704, and 163.9616 knots respectively.

### 4.3. Error in Interpolation

#### 4.3.1. Newton Forward Interpolation

To estimate the error in Newton Forward Interpolation, we can generate v-speeds for a known temperature and compare the calculated values with the given values in the above-mentioned table. The known values of  $V_1$ ,  $V_R$ , and  $V_2$  speeds at 17 degrees Celsius for calm winds (winds not blowing) are 155, 162 and 163 respectively. On applying Newton Forward Interpolation, we get the  $V_1$ ,  $V_R$  and  $V_2$  speeds to be 155.7216, 162.6639 and 164.0585 knots respectively. Hence, the percentage error for  $V_1$ ,  $V_R$  and  $V_2$  is 0.46%, 0.40% and 0.649% respectively.

It is to be noted that the values of OAT taken for this calculation are taken in intervals of 8, starting from 13 to 77.

4.3.2. Bessel interpolation

To estimate the error in Bessel Interpolation, we can generate v-speeds for a known temperature and compare the calculated values with the given values in the above-mentioned table. The known values of  $V_1$ ,  $V_R$ , and  $V_2$  speeds at 17 degrees Celsius for calm winds (winds not blowing) are 155, 162 and 163 respectively. On applying Bessel Interpolation, we get the  $V_1$ ,  $V_R$  and  $V_2$  speeds to be 155, 162 and 163 knots respectively.

```

143 6 0 -4 8 -173
149 6 -4 4 -165
155 2 0 -161
157 2 -161
159 -159
0
Value at 0 is 155.0
PS E:\Interpolation Paper\NTCC\Codes\Python>
    
```

```

Fig. 15: Error in  $V_R$  speed using Bessel Interpolation

Hence, for Bessel Interpolation, the error is 0% for all the 3 V-speeds.

## 5. Conclusion:

The method to calculate takeoff speed using suitable interpolation presented in this paper is highly accurate with negligible errors of 0.46%, 0.40% and 0.649%. Due to the high level of precision, the proposed methodology for calculating takeoff speeds can be implemented without any safety concerns. Future research will investigate the accuracy of curve fitting to calculate the takeoff speeds using RTOW charts.
